Assignment 6B

Aim

Write a program to implement insert, delete and traversal on a doubly linked list.

Theory

A doubly linked list is a type of linked list where each node contains part data, a pointer to the next node and a pointer to the previous node. This allows traversal in both forward and backward directions.
Insertion and deletion are easier compared to a singly linked list because we can directly access the previous node using the extra pointer. however it requires more memory since each node stores two links instead of one.

Insertion

To insert in a doubly linked list, a new node is created and its next and previous pointers are adjusted properly. The surrounding nodes links are also updated so that the new node is correctly connected from both sides.

Traversal

Traversal can be done from start to end by checking the next node and it is done from end to start by checking the

previous node.

Time complexity

O(n) for ~~insertion~~ ~~and~~ deletion and insertion ~~O(n) for deletion~~ as the linked list is sorted and it iterates until the correct position.

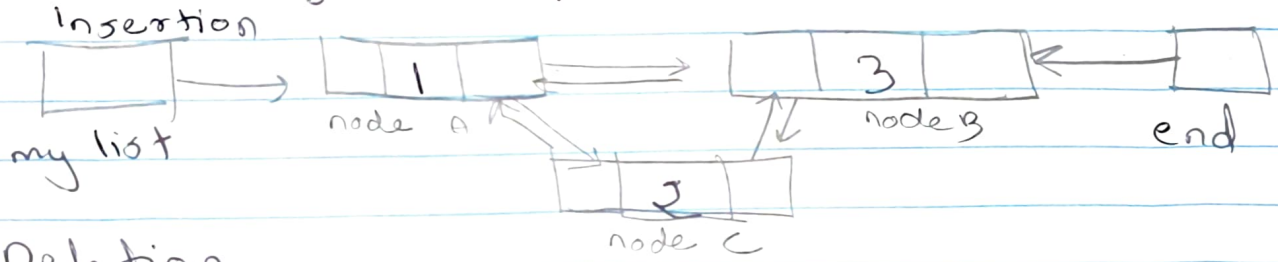
O(n) - Traversal as it iterates over the entire linked list.

Conclusion.

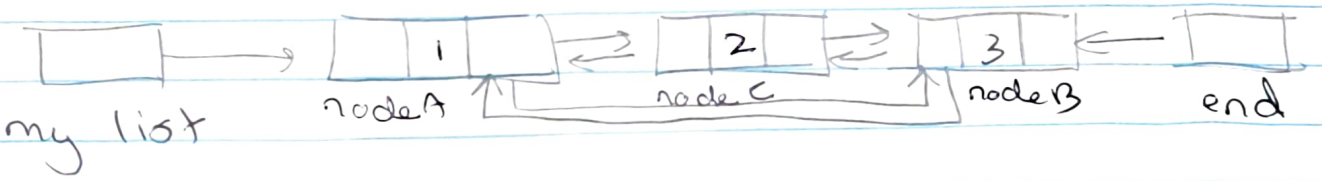
The concept is applied to evaluate problems in a variety of applications.

Insertion

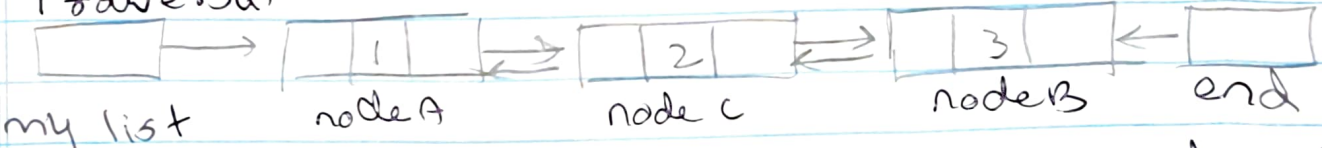
e.g.



Deletion



Traversal



It can be done from start to end and end to start
